10 3 CROSS-REFERENCE TO RELATED APPLICATION

11 This patent application has as parent application the patent application C99-00214/25.02.1999  
12 registered with the State Office for Inventions and Trademarks (OSIM) in Bucharest, Ro-  
13 mania. The present application is the US national stage of the international application  
14 PCT/IB00/00189 registered with the International Patent Office in Geneva.

15 4 BACKGROUND OF THE INVENTION

16 4.1 FIELD OF THE INVENTION

17 The invention relates to a common component of:

18     • Speech Recognition, more particularly to the fields of Keyword Spotting and decoding,

19     • Segments Alignment for DNA and proteins,

20     • Recognition of Objects in Images,

21 4.2 DESCRIPTION OF THE RELATED ART

22 This invention addresses the problem of *keyword spotting (KWS)* in unconstrained speech  
23 without explicit modeling of non-keyword segments (typically done by using filler HMM  
24 models or an ergodic HMM composed of context dependent or independent phone models  
25 without lexical constraints). Several methods (sometimes referred to as “sliding model meth-  
26 ods”) tackling this type of problem have already been proposed in the past. E.g., they use  
27 Dynamic Time Warping (DTW) or Viterbi matching allowing relaxation of the (begin and  
28 endpoint) constraints. These are known to require the use of an “appropriate” normaliza-  
29 tion of the matching scores since segments of different lengths have then to be compared.  
30 However, given this normalization and the relaxation of begin/endpoints, straightforward  
31 Dynamic Programming (DP) is no longer optimal (or, in other words, the DP optimality  
32 principle is no longer valid) and has to be adapted, involving more memory and CPU. In-  
33 deed, at any possible ending time  $e$ , the match score of the best warp and start time  $b$  of  
34 the reference has to be computed (for all possible start times  $b$  associated with unpruned

35 paths). Finally, this adapted DP quickly becomes even more complex (or intractable) for  
36 more advanced scoring criteria (such as the confidence measures mentioned below).

37 Work in the field of confidence level, and in the framework of hybrid HMM/ANN systems  
38 has shown that the use of accumulated local posterior probabilities (as obtained at the  
39 output of a multilayer perceptron) normalized by the length of the word segment (or, better,  
40 involving a double normalization over the number of phones and the number of acoustic  
41 frames in each phone) was yielding good confidence measures and good scores for the re-  
42 estimation of  $N$ -best hypotheses. However, so far the evaluation of such confidence measures  
43 involved the estimation and rescoring of  $N$ -best hypotheses.

44 KWS methods without filler models have in common the selection of a subsequence of  
45 the utterance to match the interesting keyword models. Let  $X = \{x_1, x_2, \dots, x_n, \dots, x_N\}$   
46 denote the sequence of acoustic vectors in which we want to detect a keyword, and let  $M$   
47 be the HMM model of a keyword  $M$  and consisting of  $L$  states  $\mathcal{Q} = \{q_1, q_2, \dots, q_\ell, \dots, q_L\}$ .  
48 Assuming that  $M$  is matched to a subsequence  $X_b^e = \{x_b, \dots, x_e\}$  ( $1 \leq b \leq e \leq N$ ) of  $X$ ,  
49 and that we have an implicit (not modeled) *garbage/filler state*  $q_G$  preceding and following  
50  $M$ , one can define (approximate) the log posterior of a model  $M$  given a subsequence  $X_b^e$  as  
51 the average posterior probability along the optimal path, i.e.:

$$\begin{aligned} 52 \quad -\log P(M|X_b^e) &\simeq \frac{1}{e-b+1} \min_{\forall Q \in M} -\log P(Q|X_b^e) \\ 53 \quad &\simeq \frac{1}{e-b+1} \min_{\forall Q \in M} \{-\log P(q^b|q_G) \\ 54 \quad &\quad - \sum_{n=b}^{e-1} [\log P(q^n|x_n) + \log P(q^{n+1}|q^n)] \\ 55 \quad &\quad - \log P(q^e|x_e) - \log P(q_G|q^e)\} \end{aligned} \tag{1}$$

56 where  $Q = \{q^b, q^{b+1}, \dots, q^e\}$  represents one of the possible paths of length  $(e-b+1)$  in  $M$ , and

57  $q^n$  the HMM state visited at time  $n$  along  $Q$ , with  $q^n \in \mathcal{Q}$ . In this expression,  $q_G$  represents  
 58 the “garbage” (filler) state which is simply used here as the non-emitting initial and final  
 59 state of  $M$ . Transition probabilities  $P(q^b|q_G)$  and  $P(q_G|q^e)$  can be interpreted as the keyword  
 60 entrance and exit penalties, but can be simply set to 1. Local posteriors  $P(q_\ell|x_n)$  can be  
 61 estimated using any of the known techniques: multi-gaussians, code-books, or as output  
 62 values of a multilayer perceptron (MLP) used in hybrid HMM/ANN systems. For a specific  
 63 sub-sequence  $X_b^e$ , expression (1) can easily be estimated by dynamic programming since the  
 64 sub-sequence and the associated normalizing factor  $(e - b + 1)$  are given. However, in the  
 65 case of keyword spotting, this expression should be estimated for all possible begin/endpoint  
 66 pairs  $\{b, e\}$  (as well as for all possible word models), and we define the matching score of  $X$   
 67 on  $M$  as:

$$68 \quad S(M|X) = -\log P(M|X_b^{e^*}) \quad (2)$$

69 where the optimal begin/endpoints  $\{b^*, e^*\}$ , and the associated optimal path  $Q^*$ , are the  
 70 ones yielding the lowest average local posterior:

$$71 \quad \langle Q^*, b^*, e^* \rangle = \operatorname{argmin}_{\{Q, b, e\}} \frac{-1}{e - b + 1} \log P(Q|X_b^e) \quad (3)$$

72 Of course, in the case of several keywords, all possible models will have to be evaluated.  
 73 A double averaging involving the number of frames per phone and the number of phones  
 74 usually yields slightly better performance when used to rescore N-best candidates:

$$75 \quad \langle Q^*, b^*, e^* \rangle = \quad (4)$$

$$76 \quad \operatorname{argmin}_{\{Q, b, e\}} \frac{-1}{J} \sum_{j=1}^J \left( \frac{1}{e_j - b_j + 1} \sum_{n=b_j}^{e_j} \log P(q_j^n|x_n) \right) \text{nonumber} \quad (5)$$

77 where  $J$  represents the number of phones in the hypothesized keyword model and  $q_j^n$  the

78 hypothesized phone  $q_j$  for input frame  $x_n$ . However, given the time normalization and  
79 the relaxation of begin/endpoints, straightforward DP is no longer optimal and has to be  
80 adapted, usually involving more memory and CPU.

81 Filler-based KWS need a simpler decoding step. Although various solutions have been  
82 proposed towards the direct optimization of (2), most of the keyword spotting approaches  
83 today prefer to preserve the optimality and simplicity of Viterbi DP by modeling the complete  
84 input and explicitly or implicitly modeling non-keyword segments by using so called filler or  
85 garbage models as additional reference models. In this case, we assume that non-keyword  
86 segments are modeled by extraneous garbage models/states  $q_G$  (and grammatical constraints  
87 ruling the possible keyword/non-keyword sequences).

88 [It is sufficient to consider only the case of detecting one keyword] Let  
89 us consider only the case of detecting one keyword per utterance at a time. In this case,  
90 the keyword spotting problem amounts at matching the whole sequence  $X$  of length  $N$  onto  
91 an extended HMM model  $\overline{M}$  consisting of the states  $\{q_G, q_1, \dots, q_L, q_G\}$ , in which a path  
92 (of length  $N$ ) is denoted  $\overline{Q} = \{\overbrace{q_G, \dots, q_G}^{b-1}, q^b, q^{b+1}, \dots, q^e, \overbrace{q_G, \dots, q_G}^{N-e}\}$  with  $(b-1)$  garbage states  
93  $q_G$  preceding  $q^b$  and  $(N-e)$  states  $q_G$  following  $q^e$ , and respectively emitting the vector  
94 sequences  $X_1^{b-1}$  and  $X_{e+1}^N$  associated with the non-keyword segments.

95 Given some estimation of  $P(q_G|x_n)$  (e.g., using probability density functions trained on  
96 non keyword utterances), the optimal path  $\overline{Q}^*$  (and, consequently  $b^*$  and  $e^*$ ) is then given  
97 by:

$$\begin{aligned} 98 \quad \overline{Q}^* &= \underset{\forall \overline{Q} \in \overline{M}}{\operatorname{argmin}} -\log P(\overline{Q}|X) \\ 99 &= \underset{\forall \overline{Q} \in \overline{M}}{\operatorname{argmin}} \{-\log P(Q|X_b^e)\} \end{aligned}$$

100 
$$-\sum_{n=1}^{b-1} \log P(q_G|x_n) - \sum_{n=e+1}^N \log P(q_G|x_n)\} \quad (6)$$

101 which can be solved by straightforward DP (since all paths have the same length). The main  
102 problem of filler-based keyword spotting approaches is then to find ways to best estimate  
103  $P(q_G|x_n)$  in order to minimize the error introduced by the approximations. Sometimes this  
104 value was defined as the average of the  $N$  best local scores while, in other approaches, this  
105 value is generated from explicit filler HMMs. However, these approaches will usually not  
106 lead to the “optimal” solution given by (2).

107 **5 BRIEF SUMMARY OF THE INVENTION**

108 The invention belongs to the technical domain of decoding, classification, alignment and  
109 matching of data.

110 The invention introduces a new method performing tasks in keyword spotting in utter-  
111 ances, detection of subsequences in chains of organic matter (DNA and proteins) and recog-  
112 nition of objects in images. The proposed methods search in an optimized way the matching  
113 that maximizes, over all the possible matchings, certain confidence measures based on nor-  
114 malized posteriors. Three such confidence measures are used, two existed in previous work  
115 in Speech Recognition, and the third one is a new one.

116 Application fields for this invention are: man-machine interfaces (using speech recogni-  
117 tion; ex: control systems, banking, flight services, etc), coordination systems (for industrial  
118 robots and automata) and development systems for pharmaceutic products.

122 7 DETAILED DESCRIPTION OF THE INVENTION

123 [The present invention introduces a fast iterative method,] = *In the following, we*  
124 *show that it is possible to define an iterative process, = referred to as Iterating Viterbi De-*  
125 *coding (IVD) with good/fast convergence properties, estimating the value of*  $P(q_G|x_n)$  *such*  
126 *that straightforward DP (6) yields exactly the same segmentation (and recognition results)*  
127 *than (3). While the same result could be achieved through a modified DP in which all pos-*  
128 *sible combinations (all possible begin/endpoints) would be taken into account, the method*  
129 *proposed below is much more efficient (in terms of both CPU and memory requirements).*

130 Compared to previously devised “sliding model” methods the first method proposed here  
131 is based on:

132 1. A matching score defined as the average observation probability (posterior) along the  
133 most likely state sequence. It is indeed believed that local posteriors are more appro-  
134 priate to the task.

135 2. The iteration of a Viterbi decoding algorithm, which does not require scoring for all  
136 begin/endpoints or N-best rescoring, and which can be proved to (quickly) converge to  
137 the “optimal” (from the point of view of the chosen scoring functions) solution without

138       requiring any specific filler models, using straightforward Viterbi alignments (similar  
139       to regular filler-based KWS, but for some versions at the cost of a few iterations).

140       The IVD method is based on a similar criterion as the filler based approaches (6), but  
141       rather than looking for explicit (and empirical) estimates of  $P(q_G|x_n)$  we aim at mathe-  
142       matically estimating its value (which will be different and adapted to each utterance) such  
143       that solving (6) is equivalent to solving (3). Thus, we perform an iterative estimation of  
144        $P(q_G|x_n)$ , such that the segmentation resulting of (6) is the same than what would be ob-  
145       tained from (3). Defining  $\varepsilon_t = -\log P(q_G|x_n)$  at iteration  $t$ , the proposed method can be  
146       summarized as follows:

147       1. Start the first iteration,  $t = 0$ , from an initial value  $\varepsilon_0 = \Pi$  (it is actually proven that  
148       the iterative process presented here will always converge to the same solution, in more  
149       or less cycles with the worst case upper bound of  $N$  iterations, independently of this  
150       initialization, e.g., with  $\Pi$  equal with a cheap estimation of the score of a “match”).

151       In one of the developed versions,  $\varepsilon_0$  is initialized to  $-\log$  of the maximum of the local  
152       probabilities  $P(q_k|x_n)$  for each frame  $x_n$ .

153       An alternative choice is to initialize  $\varepsilon_0$  to a pre-defined threshold score,  $T$ , that expres-  
154       sion (1) should reach to declare a keyword “matching” (see step 4 below). In this last  
155       case, if  $\varepsilon_1 > \varepsilon_0$  at the first iteration, then we can (as proven) directly infer that the  
156       inmatch will be rejected, otherwise it will be accepted.

157       2. Given the estimate  $\varepsilon_t$  of  $P(q_G|x_n)$  at current iteration  $t$ , find the optimal path  $\langle \overline{Q}_t, b_t, e_t \rangle$   
158       according to (6) and matching the complete input.

159     3. Estimate the value of  $\varepsilon_{t+1}$  to be used in the next iteration as the average of the local  
160     posteriors along the optimal path  $Q_t$  (matching the  $X_{b_t}^{e_t}$  resulting of (6) on the keyword  
161     model) i.e.:

162     
$$\varepsilon_{t+1} = -\frac{1}{(e_t - b_t + 1)} \log P(Q_t | X_{b_t}^{e_t}) \quad (7)$$

163     4. Increment  $t$  and return to (2) iterating until convergence is detected. If we are not  
164     interested in the optimal segmentation, this process could also be stopped as soon as it  
165     reaches a  $\varepsilon_{t+1}$  lower than a (pre-defined) minimum threshold,  $T$ , below which we can  
166     declare that a keyword has been detected.

167     Correctness and convergence proof of this process and generalization to other criteria, are  
168     available: each IVD iteration (from the second iteration) will decrease the value of  $\varepsilon_t$ , and the  
169     final path yields the same solution than (3). The above method has a very good experimental  
170     convergence speed (3-5 iterations in our tests). For one version of IVD (when  $\varepsilon_0$  is initialized  
171     using the acceptance threshold,  $T$ ), the detection is decided after one single step.

172     A version with the same effort but suboptimal results is proposed in the following para-  
173     graph. Let  $T(\bar{M}, X)$  be a matrix holding the HMM emission probabilities for an utterance  
174      $X$  whose time-frames define the columns, and where the states of the hypothesized word  
175      $W$  define the rows. When using the standard DP, one computes for each element of the  
176     matrix  $T(\bar{M}, X)$  at frame  $k$  of  $X$  and state  $s$  of  $\bar{M}$  three values:  $S_{ks}$ ,  $L_{ks}$  and  $C_{ks}$ , where  
177      $S_{ks}$  corresponds to the sum of the entries on the optimal path that leads to the entry,  $L_{ks}$   
178     holds the length of the optimal path computed so far, and  $C_{ks}$  is the estimation of the cost  
179     on the optimal expanded path. By a path leading to an entry  $T(k, s)$  we mean a sequence  
180     of entries in the table  $T$ , such that there is exactly an entry for each time frame  $t \leq k$ . At

181 each entry  $T(k, s)$ , DP selects a locally optimal path noted  $P_{ks}$ . At each step  $k$ , we consider  
182 all pairs of entries of table  $T(\bar{M}, X)$  of type  $T(k, s)$ ,  $T(k - 1, t)$ . We update for each such  
183 pair, the current cost  $C_{ks}$  (initially  $\infty$ ), by comparing it with the alternative given by:

$$S_{ks} = S_{(k-1)t} - \log p(s|x_k)p(s|t)$$

184

$$L_{ks} = L_{(k-1)t} + 1, \forall t > 0, t \leq L$$

185

$$C_{ks} = \frac{S_k}{L_k} \quad (8)$$

187 wanting to have at step  $k$  the path  $P_{ks}$  from the paths  $P_{(k-1)t}$  that minimizes  $C_{NL}$ . With  
188 DP, one will choose the  $P_{ks}$  with minimal  $C_{ks}$ .

189 This version can yield suboptimal results since the optimality principle is not respected  
190 by the expression 8. The optimality principle of Dynamic Programming requires that the  
191 path to the frame  $k - 1$  that minimizes  $C_{NL}$ , also minimizes  $C_{ks}$  for an entry at frame  $k$  of  
192 table  $T(\bar{M}, X)$ .

193 Another technique that is suboptimal in time and/or quality is obtained from the previous  
194 one adopting a beam-search approach and a set of safe prunings. The Dynamic Programming  
195 can be viewed as a set of safe prunings that are applied at each entry of the DP table and  
196 has the property that only one alternative is maintained. Dynamic Programming cannot be  
197 used, since the principle of optimality is not respected. The following types of safe pruning  
198 that can be done are introduced by the present invention. Within the current invention we  
199 found a set of safe prunings as follows: we have proved that if at a frame  $a$  we have two paths  
200  $P'_a$  and  $P''_a$  with  $S''_a < S'_a$  and  $L'_a < L''_a$ , then at no frame  $c \geq a$  will a path  $P''_c$  be forsaken for  
201 a path  $P'_c$  if  $P'_a \subset P'_c$ ,  $P''_a \subset P''_c$  and  $P'_c \setminus P'_a \equiv P''_c \setminus P''_a$ . We will note the order relation as  $P''_a \prec P'_a$ .

202 We have further shown that a path  $P'$  may be safely discarded only when we know a lower  
203 cost one,  $P''$ .

204 
$$P' \prec P'' \Rightarrow C'_k < C''_k \quad (9)$$

205 Thus, the method described in following method computes  $S(M, X)$  and  $Q^*$  from equa-  
206 tion (3). By ordering the set of paths, according to Equation 9, we only need to check the  
207 step (1.1) of the following method up to the eventual insertion place. The last paths are  
208 candidates for pruning in step (1.2). In order for the pruning to be acceptable, we will prune  
209 only paths that were too long on the last state. An additional counter for each path is  
210 needed for storing the state length. This counter is reset when an entry from another row  
211 is added and is incremented at each advance with a frame. The following steps detail this  
212 method for a model  $W$  and an utterance  $X$ :

213 a) Initialize all elements of a matrix,  $\text{SetOfPaths}(1..N, 1..K)$ , to  $\emptyset$

214 b) For all frames from 1 to  $N$ , for all states from 1 to  $K$ , for all candidates  $p_i$  in  
215  $\text{SetOfPaths}(\text{frame-1}, 1..K)$ :

216 – For all  $p_j$  in  $\text{SetOfPaths}[\text{frame}, \text{state}]$ , if  $p_i \prec p_j$  then delete  $p_j$  (1.1), and if  $p_j \prec p_i$   
217 then continue step b) (1.2)

218 – Insert  $p_i$  in  $\text{SetOfPaths}[\text{frame}, \text{state}]$

219 c) Select  $\text{SetOfPaths}[\text{frame}, K]$  as the best of the candidates

220 The next method builds on the previous technique and is a fast procedure for maximizing  
221 a more complex confidence measure that yields better results in practice. The corresponding

222 confidence measure is defined as:

$$223 \quad \frac{1}{NVP} \sum_{h_i \in VP} \frac{\sum_{pst \in h_i} -\log(pst)}{length(h_i)} \quad (10)$$

224 where NVP stands for the *number of visited phonemes* and VP stands for the *set of visited phonemes*. An average is computed over all posteriors  $pst$  of the emission probabilities for the 226 time frames matched to the visited phoneme  $h_i$ . The function  $length(h_i)$  gives the number of 227 time frames matched against  $h_i$ . This method uses a breath first Beam Search algorithm. It 228 exploits a set of reduction rules and certain normalizations. For the state  $q_G$ , in this method, 229 the logarithm of the emission posterior is equal with zero. For each frame  $e$  and for each 230 state  $s$ , the set of paths/probabilities of having the frame  $e$  in the state  $s$  is computed as 231 the first  $\mathcal{N}$  maxima ( $\mathcal{N}$  can be finite) of the confidence measure for all paths in HMM  $\overline{M}$  of 232 length  $e$  and ending in the state  $s$ . The paths that according to the reduction rules will loose 233 the final race when compared with another already known path, will be deleted as well. Let 234 us note  $a_1, p_1, l_1$ , respectively  $a_2, p_2$  and  $l_2$  the confidence measure for the previously visited 235 phonemes, the posterior in the current phoneme and the length in the current phoneme for 236 the path  $Q_1$ , respectively the path  $Q_2$ . The rules that can be used for the reduction of the 237 search space by discarding a path  $Q_1$  for a path  $Q_2$  are in this case any of the next ones:

238     1.  $l_2 \geq l_1, A > 0, B \leq 0$  and  $L_c^2 A + L_c B + C \geq 0$

239     2.  $l_2 \geq l_1, A \geq 0, B \geq 0$  and  $C \geq 0$

240     3.  $l_2 \geq l_1, A \leq 0, C \geq 0$  and  $L^2 A + LB + C \geq 0$

241     4.  $l_2 \geq l_1, A = 0, B < 0$  and  $LB + C \geq 0$

242 where  $A = a_1 - a_2$ ,  $B = (a_1 - a_2)(l_1 + l_2) + p_1 - p_2$ ,  $C = (a_1 - a_2)l_1 l_2 + p_1 l_2 - p_2 l_1$ ,  $L =$   
243  $L_{max} - \max\{l_1, l_2\}$ ,  $L_c = -B/2A \geq 0$  and  $L_{max}$  is the maximum acceptable length for a  
244 phoneme. By discarding paths only if one of the above rules is satisfied, the optimum defined  
245 by the confidence measure with double normalization can be guaranteed, if no phone may be  
246 avoided by the HMM  $M$ . Any HMM may be decomposed in HMMs with this quality. The  
247 4-th rule is included in the 3-rd and its test is useless if the last one was already checked.  
248 The first test,  $l_2 \geq l_1$  tells us if  $Q_2$  has chances to eliminate  $Q_1$ , otherwise we will check  
249 if  $Q_1$  eliminates  $Q_2$ . These tests were inferred from the conditions of maintaining the final  
250 maximal confidence measure while reduction takes place. In order to use the method of  
251 double normalization without decomposing HMMs that skip some phonemes, the previous  
252 rules are modified taking into account the number of visited phonemes for any path  $F_1$   
253 respectively  $F_2$  and the number of phonemes that may follow the current state. A simplified  
254 test can be:

255 •  $l_2 \geq l_1$ ,  $A \geq 0$ ,  $p_1 \geq p_2$  respectively  $F_2 \geq F_1$  for the HMMs that skips phonemes.

256 This test is weaker than the 2<sup>nd</sup> reduction rule. For example a path is eliminated by a second  
257 path if the first one has an inferior confidence measure (higher in value) for the the previous  
258 phonemes, a shorter length and the minus of the logarithm of the cumulated posterior in  
259 the current phoneme also inferior (higher in value) to that of the second one. An additional  
260 confidence measure based on the maximal length,  $L_{max}$ , and on the maximum of the minus  
261 of the logarithm of the cumulated and normalized posterior in phoneme,  $P_{max}$ , can be used  
262 in order to limit the number of stored paths.

263 •  $p > L_{max} P_{max}$  in any state

264     •  $\frac{p}{l} > P_{max}$  at the output from a phoneme  
265 where p and l are the values in the current phoneme for the minus of the logarithm of  
266 cumulated posterior and for the length of the path that is discarded. These tests allow for  
267 the elimination of the paths that are too long without being outstanding, respectively of  
268 the paths with phonemes having unacceptable scores, otherwise compensated by very good  
269 scores in other phonemes. If  $N$  is chosen equal with one, the aforementioned rules are no  
270 longer needed, but always we propagate the path with the maximal current estimation of  
271 the confidence measure. The obtained results are very good, even if the defined optimum is  
272 guaranteed for this method only when  $N$  is bigger than the length of the sequence allowed  
273 by  $L_{max}$  or of the tested sequence. The same approach is valid for the simple normalization,  
274 where the HMM for the searched word will be grouped into a single phoneme.

275     The present invention can exploit a newly designed a confidence measure, version named  
276 "Real Fitting", that represents differently the exigencies of the recognition. Since the  
277 phonemes and the absent states can be modeled by the used HMMs, we find it interest-  
278 ing to request the fitting of each phoneme in the model with a section of the sequence.  
279 Therefore, we measure the confidence level of a subsequence as being equal with the max-  
280 imum over all phonemes of the minus of the logarithm of the cumulated posterior of the  
281 phone, normalized with its length:

$$282 \quad \max_{phonem \in Visited\ Phonems} \frac{\sum_{phonem} - \log(posterior)}{phonem\ length} \quad (11)$$

283 The rule that may be used in this framework for the reduction of the number of visited paths  
284 is:

285     •  $Q_2$  is discarded in favor of another path  $Q_1$  if the confidence measure of the Real

286 Fitting for the previous phonemes is inferior (higher in value) for  $Q_2$  compared with  
287  $Q_1$ , and if  $p_1 \leq p_2$  and  $l_2 \leq l_1$ .

288 where  $p_1, l_1$ , respectively  $p_2, l_2$  represent the minus of the logarithm of the cumulated poste-  
289 rior respectively the number of frames in the current phoneme for the path  $Q_1$  respectively  
290  $Q_2$ . Similarly to the previous method, the set of visited paths can be pruned by discarding  
291 those where:

292 •  $p > L_{max} P_{max}$  in any state

293 •  $\frac{p}{l} > P_{max}$  at the output from a phoneme

294 where  $p$  and  $l$  are the values in the current phoneme for the minus of the logarithm of the  
295 cumulated posterior and for the length of the path that is discarded. We recall that the  
296 meaning of the constants are the maximal length  $L_{max}$ , respectively the accepted maxima  
297 of the minus of the logarithm of the cumulated and normalized posterior in phoneme,  $P_{max}$ .

298 This invention thus proposes a new method for keyword spotting, based on recent ad-  
299 vances in confidence measures, using local posterior probabilities, but without requiring the  
300 explicit use of filler models. A new method, referred to as *Iterating Viterbi Decoding (IVD)*,  
301 to solve the above optimization problem with a simple DP process (not requiring to store  
302 pointers and scores for all possible ending and start times). Other three new beam-search  
303 algorithms corresponding to three different confidence measures are also proposed.

304 To summarize, the object of the invention consists of:

305 • Method of recognition of a subsequence using a direct maximization of confidence  
306 measures.

307     • The method of IVD for directly maximizing the confidence measures based on simple  
308         normalization.

309     • The use of the confidence measure and method of recognition named ‘Real Fitting’,  
310         based on individual fitting for each phoneme.

311     • Methods of recognition using simple and double normalization by:  
312         • combining these measures with additional confidence measures mentioned here, respec-  
313             tively the maximal length and real matching limitation.

314     • The use of the aforementioned methods in keyword recognition.  
315     • The use of the aforementioned methods in subsequence recognition of organic matter.  
316     • The use of the aforementioned methods in recognition of objects in images.

317     DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

318     Execution: The method can be performed using a personal computer or can be imple-  
319         mented in specialized hardware.

320     1. A representation under the form of an HMM is obtained for the subsequences that are  
321         looked for (word, protein profile, section of an image of the object).

322     2. A tool will be obtained (eventually trained Ex: for speech recognition) for the esti-  
323         mation of the posteriors. For example multi-Gaussians, neuronal networks, clusters,  
324         database with Generalized Profiles and mutation matrices (PAM, BLOSSUM, etc.).

325     3. One of the proposed algorithms should be implemented. They yield close performance  
326       but the method of Real Fitting coupled with a well checked dictionary should perform  
327       best.

328     For the first algorithm (IVD)

329       (a) The classic algorithm of Viterbi is implemented with the modification that, for  
330       each pair  $P = \langle sample, state \rangle$  one propagates the time-frame of transition be-  
331       tween the state  $q_G$  and the states of the HMM  $M$  for the path that arrives at P.  
332       These are inherited from the path that wins the entrance in the pair P, excepting  
333       for the moment when their decision is taken, namely when they receive the index  
334       of the corresponding sample.

335       (b)  $w = -\log P(M|X_b^e)$  is computed by subtracting from the cumulated posterior  
336       that is returned by the Viterbi algorithm for the path  $Q_{b_t}^{e_t}$ , the value  $(N - (e_t -$   
337        $b_t + 1)) * \varepsilon_t$  corresponding to the contribution of the states  $q_G$  and dividing the  
338       result through  $e_t - b_t + 1$ .  $e_t - b_t + 1$  from the previous formula can be factored  
339       outside the fraction.

340       (c) The initialization of  $\varepsilon$  is made with an expected mean value. One can use the  $w$   
341       that is computed when the state  $q_G$  is associated with an emission posterior equal  
342       to the average of the best  $K$  emission probabilities of the current sample as done  
343       in the well-known “garbage on-line model”. In this case, K is trained using the  
344       corresponding technique.

345     The next 'Beam search' algorithms, are implemented according to the description in

346 the corresponding sections. For each pair  $P = \langle sample, state \rangle$  one computes for each  
347 corresponding path the sum and length in the last phoneme, as well as the sum over  
348 the normalized cumulated posteriors of the previous phonemes (and their number).  
349 Also, the entrance and exit samples into the HMM  $M$  are computed and propagated  
350 like in the previous method, in order to ensure the localization of the subsequence.

351 4. If one searched entity (keyword, sequence, object) can have several HMM models, all  
352 of them are taken into consideration as competitors. This is the case of the words  
353 with several pronunciations (or of the objects that have different structures in different  
354 states, for the recognition in images).

355 After the computation of the confidence measure for each model of the subsequences,  
356 one eliminates those with a confidence measure in disagreement with a 'threshold' that  
357 is trained for the configuration and the goal of the given application. For example, for  
358 speech recognition with neuronal networks and minus of the logarithm of the posteriors,  
359 the 'threshold' is chosen in the wanted point of the ROC curve obtained in tests.

360 5. The remained alternatives are extracted in the order of their confidence measure and  
361 with the elimination of the conflicting alternatives until exhaustion. Each time when  
362 an alternative is eliminated, the searched entity with the corresponding HMM is re-  
363 estimated for the remaining sections in the sequence in which the search is performed.  
364 If the new confidence measure passes the test of the 'threshold', then it will be inserted  
365 in the position corresponding to its score in the queue of alternatives.

366 6. The successful alternatives can undergo tests of superior levels like for example a

367 question of confirmation for speech recognition, opinion of one operator, etc.

368 7. For objects recognition in images:

369 Posteriors are obtained by computing a distance between the color of the model and  
370 that of element in the section of the image. If the context requires, the image will be  
371 preprocessed to ensure a certain normalization (Ex: changeable conditions of light will  
372 make necessary a transformation based on the histogram).

373 The phonemes of the speech recognition correspond to parts of the object. The struc-  
374 ture (existence of transitions and their probabilities) can be modified, function of the  
375 characteristics detected along the current path. For example, after detecting regions  
376 of the object with certain lengths, one can estimate the expected length of the remain-  
377 ing regions. Thus, the number of the expected samples for the future states can be  
378 established and the HMM attached to the object will be configured accordingly.

379 A direction is scanned for the detection of the best fitting and afterwards, other direc-  
380 tions will be scanned for discovering new fittings, as well as for testing the previous  
381 ones. The final test will be certified by classical methods such as cross-correlation or  
382 by the analysis of the contours in the hypothesized position.

383 To mention some examples for the application of the proposed method:

384 • The recognition of keywords begins to be used in answering automates of banking  
385 system as well as telephone and automates for control, sales or information. The  
386 method offers a possibility to recognize keywords in spontaneous speech with multiple  
387 speakers.

388     • The recognition of DNA sequences is important for the study of the human Genome.

389         One of the biggest problem of the involved techniques consists in the high quantity of

390         data that have to be processed.

391     • The recognition of objects in images is used, among others, in cartography and in the

392         coordination of industrial robots. The method allows a quick estimation of the position

393         of the objects in scenes and can be validated with extra tests, using classical methods

394         of cross-correlation.

395 WE CLAIM:

396 1. (canceled) rewritten/re-presented in claim 5

397 2. (canceled) rewritten/re-presented in claim 6

398 3. (canceled) rewritten/re-presented in claim 7

399 4. (canceled) rewritten/re-presented in claim 8

400 5. (canceled) rewritten/re-presented in claim 9

401 6. (canceled) rewritten/re-presented in claim 10

402 7. (canceled) rewritten/re-presented in claim 11

403 8. (canceled) rewritten/re-presented in claim 12

404 9. (re-presented - formerly independent claim 5) A method of recognizing an observed

405 subsequence as being generated by one of a set of Hidden Markov Models (HMM),

406 characterized by:

407 • the fact that it searches the subsequence,  $Q$ , that offer the minimization of an

408 inverse confidence measure, over all possible matchings,

409 • where the inverse confidence measure is one of

410 1) the accumulated posterior, normalized with the length of the matched sub-

411 sequence  $X_b^e$  (aka. 'simple normalization')

$$412 \quad \frac{-1}{e - b + 1} \log P(Q|X_b^e)$$

413        2) partitioning the states in a HMM into phonems, having a function  
414              Phonemes( $Q$ ) that returns the segmentation of a path  $Q$  in the HMM into  
415              phonems, and computing one of:

416        2a) the worst average match in a phoneme, called 'real fitting',

417              
$$\operatorname{argmin}_Q \left( \max_{Q \in \text{Phonemes}(Q)} \frac{\sum_{q^k \in Q} - \log P(q^k | x_k)}{|\{k | q^k \in Q\}|} \right)$$

418        2b) double normalization of the accumulated posterior over the number of  
419              phonemes,  $J$ , and over the number of acoustic samples,  $e_j - b_j + 1$ , where  
420               $e_j$  is the time frame where  $Q$  enters phoneme  $j$ , and  $b_j$  is the exit time  
421              frame from each phoneme,  $j$ ,

422              
$$\frac{-1}{J} \sum_{j=1}^J \left( \frac{1}{e_j - b_j + 1} \sum_{n=b_j}^{e_j} \log P(q_j^n | x_n) \right)$$

423        • and allows for the optional revaluation of the alternatives that offer the high-  
424              est scores of a mentioned confidence measure on the basis of another confidence  
425              measure,

426        • and when based on the confidence measure called 'simple normalization' uses a  
427              method that applies Viterbi decoding for a HMM obtained by extending the initial  
428              one with a filler state just after start and one just before the termination state,  
429              and estimates the emission probability of the filler states in an iterative manner  
430              as being equal to the inverse confidence measure in the previous iteration,  
431              and where the emission probability in the filler states in the first iteration can be  
432              initialized to any floating point number, but the iteration stops:

433 i at convergence yielding the estimation of a keyword's boundaries and score  
434 as the obtained boundaries and score of non-filler states of the HMM,  
435 ii when the confidence measure descends under a threshold value, T, estimating  
436 only the keyword existence,  
437 iii when the emission probability of filler states,  $\varepsilon_0$  is initialized with T and is  
438 reestimated, as value of  $\varepsilon_1$  at the end of the first iteration, to be higher than  
439 T deciding keyword inexistence,

440 • or for any of the three confidence measures: 'simple normalization', 'double nor-  
441 malization' or 'real fitting', uses a beam-search-like algorithm that considers the  
442 emission probability of the filler state as zero, computes progressively for each  
443 pair of sample and state of HMM a set of possible alternatives paths to reach it,  
444 the computation of this set is based on the sets of paths that lead to the states that  
445 can be associated to the previous sample and extended with transitions allowed  
446 by the analyzed HMM,  
447 where this set can be reduced by using appropriate (safe) rules for the given  
448 confidence measure, ensuring the correctness of the inference,  
449 and where this set can be also reduced by using heuristics, for speeding up the  
450 computation despite the risk of reducing the theoretical quality of the recognition,  
451 heuristics of which a fast version stores only the best match,  
452 and for all confidence measures one can prune the set of alternatives with safe rules  
453 guaranteeing optimality, where:

454     • the 'simple normalization' confidence measure with beam-search is used with a  
455           safe pruning that discards a path  $Q_1$  given the existence of a path  $Q_2$  whenever  
456            $S_2 < S_1$  and  $L_1 < L_2$ , where  $S_1$  and  $L_1$  respectively  $S_2$  and  $L_2$  are the minus of  
457           the cumulated log of posteriors along the paths, and the lengths of the paths, for  
458           the paths  $Q_1$  respectively  $Q_2$ , and which can be optimized by sorting competing  
459           paths based on their cost

460     • the 'double normalization' confidence measure on HMMs where no path skips any  
461           phoneme is used with a safe pruning that discards a path  $Q_1$  given the existence  
462           of a path  $Q_2$  whenever one of the following tests succeed:

463       (a)  $l_2 \geq l_1$ ,  $A > 0$ ,  $B \leq 0$  and  $L_c^2 A + L_c B + C \geq 0$

464       (b)  $l_2 \geq l_1$ ,  $A \geq 0$ ,  $B \geq 0$  and  $C \geq 0$

465       (c)  $l_2 \geq l_1$ ,  $A \leq 0$ ,  $C \geq 0$  and  $L^2 A + LB + C \geq 0$

466       (d)  $l_2 \geq l_1$ ,  $A = 0$ ,  $B < 0$  and  $LB + C \geq 0$

467           where we denote by  $a_1$ ,  $p_1$ ,  $l_1$ , respectively by  $a_2$ ,  $p_2$  and  $l_2$  the confidence measure  
468           for the previously visited phonemes, the posterior in the current phoneme and  
469           the length in the current phoneme for the path  $Q_1$ , respectively the path  $Q_2$ ,  
470           and we also use the notations  $A = a_1 - a_2$ ,  $B = (a_1 - a_2)(l_1 + l_2) + p_1 - p_2$ ,  
471            $C = (a_1 - a_2)l_1 l_2 + p_1 l_2 - p_2 l_1$ ,  $L = L_{max} - \max\{l_1, l_2\}$ ,  $L_c = -B/2A$  and  $L_{max}$  is  
472           the maximum acceptable length for a phoneme,

473     • the 'double normalization' confidence measure on HMMs where some paths skip  
474           phonemes is used with a safe pruning that discards a path  $Q_1$  given the existence  
475           of a path  $Q_2$  whenever  $l_2 \geq l_1$ ,  $A \geq 0$ ,  $p_1 \geq p_2$  respectively  $F_2 \geq F_1$ ,

476 where  $F_1$  respectively  $F_2$  are the number of visited phonemes for paths  $Q_1$  and  
477  $Q_2$ ,

478 • the 'real fitting' is used with the safe pruning:  $Q_2$  is discarded in favor of another  
479 path  $Q_1$  if the confidence measure of the Real Fitting for the previous phonemes  
480 is inferior (higher in value) for  $Q_2$  compared with  $Q_1$ , and if  $p_1 \leq p_2$  and  $l_2 \leq l_1$ ,  
481 where  $p_1, l_1$ , respectively  $p_2, l_2$  represent the minus of the logarithm of the cumu-  
482 lated posterior respectively the number of frames in the current phoneme for the  
483 path  $Q_1$  respectively  $Q_2$ ,

484 • and besides the previously mentioned safe pruning, heuristic prunings are also  
485 used for removing paths when  $p > L_{max}P_{max}$  in any state or when  $\frac{p}{l} > P_{max}$  at  
486 the output from a phoneme,

487 where  $p$  and  $l$  are the values in the current phoneme for the minus of the logarithm  
488 of cumulated posterior and for the length of the path that is discarded.

489 10. (re-presented - formerly dependent claim 6) The method of claim 9, where the method  
490 is used to estimate the existence of keywords and their position in utterances, using  
491 Hidden Markov Models that model keywords.

492 11. (re-presented - formerly dependent claim 7) The method of claim 9, where the method  
493 is used to estimate the existence of biomolecular subsequences and their position in the  
494 chains of DNA using hidden Markov models to model the searched subsequences, and  
495 where these models can be obtained by trivial translation from generalized profiles.

496 12. (re-presented - formerly dependent claim 8) The method of claim 9, where it carries out

497       the estimation of the existence of objects and their position in images, characterized  
498       by the fact that

499       • it uses models of objects as subsequences represented by Hidden Markov Models,

500       • namely sections through views of objects are modeled by Hidden Markov Models,

501       • it uses emission probabilities based on a distance computed between colors, sim-

502       ple distances being yield by a Gaussian with median at the target color, or a

503       normalized inverse of the Euclidean distance in the RGB space,

504       • wherein the Hidden Markov Models that model the objects can be structured of

505       distinct regions, that play in the frame of the method the role of the phonemes

506       in claim 9,

507       • and wherein the models of the objects can be modified in a dynamic manner during

508       decoding with respect to the transition properties (existence and probability) on

509       the basis of the so far accumulated information in the process.

## 510 8 ABSTRACT OF THE DISCLOSURE

511 The invention belongs to the technical domain of decoding, classification, alignment and  
512 matching of data.

513 The invention introduces a new method performing tasks in keyword spotting in ut-  
514 terances, detection of subsequences in chains of organic matter (DNA and proteins) and  
515 recognition of objects in images. The proposed method searches in an optimized way the  
516 matching that maximizes, over all the possible matchings, certain confidence measures based  
517 on normalized posteriors. Three such confidence measures are used, two existed in previous  
518 work in Speech Recognition, and the third one is a new one.

519 Application fields for this invention are: man-machine interfaces (using speech recogni-  
520 tion; ex: control systems, banking, flight services, etc), coordination systems (for industrial  
521 robots and automata) and development systems for pharmaceutic products.
